chapter 1. how we implement session
Session works like a tag or id. When a user visit our site without a session, we tell him to login before enjoying our service. After user supply valid user name and password, we create a session for it. This user's session is updated every time it request a page. By verifying a session we can track our user without a user's credential. it's really convenient. After user request for logout, we remove the session.

chapter 2. what session do.
Session can be created after user visit our site. We can tracking visitors if we want that whether they login or not, and even without sensing. A special session is created after user supply user name and password. We can verify the visitor/user in sequence contexts even without user's credential like user name/password which enhances the security. In mobile internet, session becomes more and more important. The net environment is usually unstable. With session, we provide better service. The Web site performance is also enhanced.

Chapter 3. some improvements
at this moment, our site is simple and crud. As for session, it's really too simple. And it's vulnerable from any kind of hackers. I think it has to be encrypted.
